## Description

This invention relates to novel aryl oxime-carbamates and carbonates having bronchodilatory and anti-inflammatory activities and being useful in the treatment of asthma.

5 Asthma is a disease in which respiratory distress is produced as a result of airway narrowing. This narrowing is caused largely by 1) the acute constriction of the respiratory smooth muscle that surrounds the airways and 2) chronic inflammation within the lung. Agents that reverse bronchospasm and prevent pulmonary inflammation are thus useful in the relief of the symptoms of asthma.

One approach for reversing bronchospasm and also inhibiting inflammation is to elevate intracellular  
10 adenosine cyclic 3':5'- monophosphate (cAMP) in respiratory smooth muscle and inflammatory cells, respectively. Agents that elevate smooth muscle cAMP concentrations induce rapid bronchodilation and inhibit the release of inflammatory mediators from activated leukocytes [see Hardman, in Smooth Muscle, An Assessment of Current Knowledge, Univ. of Texas Press, (1981); and Nielson et al., American Review of Respiratory Disease,

15

137,

25 (1988)]. By virtue of their dual mechanisms of action, these compounds are expected to be highly effective as anti-asthmatic drugs.

Cyclic AMP concentrations within the living cell are determined by both the rate of its synthesis by adenylate cyclase and the rate of its degradation by phosphodiesterases (PDEs). Thus, either stimulating adenylate cyclase or inhibiting PDEs in pulmonary tissues can result in anti-asthmatic activities. This invention relates to compounds that inhibit a specific PDE, often called PDE IV, which selectively  
25 metabolizes cAMP and which is insensitive to the modulatory effects of guanosine cyclic 3':5' monophosphate (cGMP) and calcium. This PDE is found in both respiratory smooth muscle and inflammatory cells, and has been demonstrated to be a principal regulator of cAMP in these tissues [see Torphy and Cieslinski, Molecular Pharmacology,

30

37,

206 (1990), and Dent et al., British Journal of Pharmacology,

35

90,

163P (1990)]. Consequently, the compounds of the invention are bronchodilatory and antiinflammatory, and exhibit activity in animal models of allergic and nonallergic asthma. However, because the compounds of  
40 the invention have not been found to inhibit other forms of PDE, they are deemed to be more selective and safer anti-asthmatics than nonselective PDE inhibitors currently used for the treatment of asthma, such as theophylline.

Substituted benzaldehydes, phenylketones and phenylketoximes are disclosed in the following references: DE-A-2655369, DE-A-3438839, WO-A-87/06576, EP-A-428302, EP-A-186817 and Chemical Abstracts  
45 96:142811 and 110:75441. Oxime carbonates are disclosed in FR-A-2244499, 2204406 and 2201885.

The invention provides novel compounds of the formula

20

R<sup>1</sup> is hydrogen, lower alkyl or

25

a is 1-3; b is 1-3; c is 0-2;

30

X, Y and Z are each, independently, a bond, O, S or NH, with the proviso that if one of X or Y is O, S or NH, the other must be a bond;

R<sup>2</sup> is amino, loweralkylamino, arylamino, loweralkoxy or aryloxy;

R<sup>3</sup> and R<sup>3'</sup> are independently hydrogen, halo, hydroxy, lower alkoxy, aryloxy, loweralkanoyloxy, amino, lower alkylamino, arylamino or loweralkanoylamino;

The terms "lower alkyl", "lower alkoxy" and "lower alkanoyl" refer to moieties having 1 to 6 carbon atoms in the carbon chain. The term "aryl" refers to aromatic moieties having 6-10 carbon atoms. The term "halo" refers to fluoro chloro and bromo.

Examples of lower alkyl when used as a group or part of a group e.g alkoxy are methyl, ethyl, propyl, isopropyl, butyl.

40

Examples of lower alkanoyloxy and lower alkanoyl-amino are groups of formula lower alkyl COO- and loweralkyl CONH- where lower alkyl is exemplified as above.

Examples of R are cycloalkyl groups of 3-7 carbon atoms such as cyclopentyl, and alkyl groups of 3 to 7 carbon atoms such as butyl. When R is a group of formula

45

50

an example of m is zero; R<sup>4</sup> and R<sup>5</sup> may be for example hydrogen;

X can be for example O; n may be for example 1, 2, or 3; and R<sup>3</sup> is exemplified by hydrogen, halo, hydroxy, acetoxy, amino or acetamido, the combination of said values being preferred.

Examples of a, b and c are 2, 1 and 1 respectively or 2, 2 and 0 respectively.

Examples of  $R^3$  are the same as for  $R^3$  above.

Preferably Z is a direct bond.

Examples of  $R^2$  are  $NH_2$ ,  $NHMe$ ,  $NHPh$ ,  $OMe$ ,  $OPh$ .

The especially preferred compounds are those having the formula

wherein

R is  $(C_3-7)$  alkyl,  $(C_3-7)$  cycloalkyl,

or

$R^1$  is hydrogen, lower alkyl or

$R^2$  is amino, loweralkylamino, arylamino, loweralkoxy or aryloxy;

$R^3$  and  $R^3$  are independently hydrogen, halo, hydroxy, acetoxy, amino or acetamido;

$o$  is 1-4; and  $p$  is 2-4.

The most preferred compounds are those in which  $R^2$  is amino.

The compounds of the invention can be prepared by a basic reaction sequence, in which in the initial step isovanillin is reacted with a suitable R group-containing derivative, to yield an isovanillin intermediate with the appropriately substituted hydroxy group:

OR

The latter is then reacted with an  $R^1$  lithium derivative or appropriate Grignard reagent, followed by oxidation with pyridinium dichromate or  $MnO_2$  to yield an appropriate ketone derivative

The ketone is then reacted with hydroxylamine hydrochloride, to yield the corresponding ketone oxime.

This ketone oxime is then reacted with appropriate reactants to yield the desired final product oxime carbamates or oxime carbonates. Thus, in order to prepare the *N*-unsubstituted oxime carbamates, an intermediate ketone oxime can be reacted with 1) chlorosulfonyl isocyanate in dry tetrahydrofuran, or with 2) trichloroacetyl isocyanate in dry tetrahydrofuran followed by reacting with ammonia, or with 3) sodium cyanate and trifluoroacetic acid in methylene chloride, or with 4) sodium cyanate and acetic acid and water:

In like manner, *N*-substituted carbamates can be prepared by using an appropriately substituted alkyl or aryl isocyanate in dry tetrahydrofuran:

Finally, the oxime carbonates can be prepared by reacting the intermediate ketone oxime with an appropriate alkyl or aryl chloroformate in pyridine and methylene chloride:

Of course, other methods of preparation, which will occur to those skilled in the art, may also be employed to prepare the compounds of this invention.

The starting materials used in the above-described preparative routes are commercially available, or can be made according to procedures taught in the chemical literature.

By virtue of possessing a double bond, the compounds of the invention possess *cis-trans* isomerism and hence the compounds of the invention embrace not only geometrical isomer mixtures, but the individual isomers as well. The isomers are designated according to the *E/Z*-system using the sequence rule.

*E/Z* isomers may generally be prepared from the corresponding oxime precursors by processes described hereinabove. *E/Z* isomers of the oximes may themselves generally be prepared by oximation of the ketone, with shorter reaction times generally favouring formation of the *Z* isomer, and longer reaction

times favouring formation of the E-isomer. The E, Z isomers can generally be separated either at the oxime stage or at the final product stage.

The E form is preferred.

Certain intermediate oximes and ketones of formula II and III as defined above are also within the scope of this invention including methods for preparing them.

In particular this invention provides (i) oximes of formula III as hereinbefore defined wherein R and R<sup>1</sup> are as defined above providing that when R<sup>1</sup> is hydrogen then R is other than C<sub>3</sub>-C<sub>7</sub> alkyl;  
(ii) compounds of formula II as defined above wherein R<sup>1</sup> is

and (iii) a compound of formula II as defined above wherein a) R<sup>1</sup> is C<sub>1</sub>-C<sub>4</sub> alkyl and R is

or

providing that the latter group has more than 8 carbon atoms when X and Y are both bonds, and further providing that R is other than PhCH<sub>2</sub>OCH<sub>2</sub>- when R<sup>1</sup> is methyl, or  
b) R<sup>1</sup> is alkyl wherein the number of carbon atoms is greater than 4 and not more than 6 and R is as herein defined.

The compounds of the invention, by virtue of their ability to inhibit PDE IV, are bronchodilatory and antiinflammatory, and are useful in the treatment of acute and chronic bronchial asthma and its associated pathology.

When the compounds of the invention are employed in the treatment of acute or chronic bronchial asthma, they can be formulated into oral dosage forms such as tablets, capsules and the like. The compounds can be administered alone or by combining them with conventional carriers, such as magnesium carbonate, magnesium stearate, talc, sugar, lactose, pectin, dextrin, starch, gelatin, tragacanth, methylcellulose, sodium carboxymethylcellulose, low melting wax, cocoa butter and the like. Diluents, flavoring agents, solubilizers, lubricants, suspending agents, binders, tablet-disintegrating agents and the like may be employed. The compounds may also be injected parenterally, in which case they are used in the form of a sterile solution containing other solutes, for example, enough saline or glucose to make the solution isotonic. For administration by inhalation or insufflation, the compounds may be formulated into an aqueous or partially aqueous solution, which can then be utilized in the form of an aerosol.

The dosage requirements vary with the particular compositions employed, the route of administration, the severity of the symptoms presented and the particular subject being treated. Treatment will generally be initiated with small dosages, less than the optimum dose of the compound. Thereafter the dosage is increased until the optimum effect under the circumstances is reached. In general, the compounds of the invention are most desirably administered at a concentration that will generally afford effective results without causing any harmful or deleterious side effects, and can be administered either as a single dose, or if desired, the dosage may be divided into convenient subunits administered at suitable times throughout the day.

Accordingly this invention also provides a pharmaceutical composition comprising a compound of formula I as defined hereinabove and a pharmaceutical carrier.

The PDE IV inhibitory effects of the compounds of the invention may be demonstrated by standard pharmacological procedures, which are described more fully in the examples given hereinafter.

These procedures illustrate the ability of the compounds of the invention to inhibit PDE IV isolated from canine trachea.

The following examples show the preparation and pharmacological testing of compounds within the invention.

A) 1-(3-Cyclopentyloxy-4-methoxyphenyl)-2-phenyl ethan-1-ol

To a magnetically-stirred solution of freshly crushed magnesium turnings (36.54 mmol, 0.888 g) in anhydrous ethyl ether (20 mL) at room temperature is added a solution of benzyl bromide (36.54 mmol, 4.35 mL) in anhydrous ethyl ether (15 mL) dropwise via addition funnel. The addition is slow at first; only 2 to 3 mL of reagent is added and the reaction mixture is heated until gas evolution is observed. Dropwise addition of benzyl bromide is begun at this point, and the reaction mixture is diluted with ethyl ether (20 mL) to prevent dimerization of the Grignard reagent. Once the addition of benzyl bromide is complete, the reaction is allowed to stir at room temperature for 1 hour and then a solution of 3-cyclopentyloxy-4-methoxybenzaldehyde (30.00 mmol, 6.61 g) in anhydrous ethyl ether (30 mL) is added dropwise at room temperature. The reaction mixture is allowed to stir at room temperature for 30 minutes and then poured into a solution of ice water (500 mL) containing concentrated H<sub>2</sub>SO<sub>4</sub> (7 mL). The aqueous mixture is extracted with ethyl acetate (2 x 300 mL) and the combined organic layers are washed with saturated NaHCO<sub>3</sub> (300 mL). The organic layer is dried (Na<sub>2</sub>SO<sub>4</sub>) and concentrated *in vacuo* to afford the title compound as a white solid (25.97 mmol, 8.06 g; 86%) of sufficient purity to be used directly in subsequent transformation.

The reaction mixture is then cooled to 0 °C and saturated NH<sub>3</sub>/acetonitrile solution (25 mL; prepared by bubbling gaseous ammonia through CH<sub>3</sub>CN at room temperature for 1 hour) is added dropwise to the reaction mixture. #### Example 14

The following assay is employed to assess the ability of the compounds of the invention to inhibit PDE IV.

A solution containing PDE IV is prepared from canine tracheal muscle as follows:

The dog is euthanized with an overdose of beuthanasia while under anesthesia induced by a 33 mg/kg IV bolus of Nembutal. The trachealis muscle is removed, cleaned of connective tissue, and minced

thoroughly. Three to four grams of tissue is then homogenized in Tris-HCl buffer (pH 7.8) using a Polytron. The homogenate is then centrifuged at 25,000 x g (4°C) for 30 minutes. The supernatant is decanted and filtered through four layers of gauze, and applied to a 40 cm x 2 cm DEAE-Sepharose column that is equilibrated with Tris-HCl buffer (pH 7.8). The column is then washed with an additional 240 mL of buffer to remove unbound proteins. PDE is eluted using 450 mL of Tris-HCl buffer containing a linear gradient of 0.0 - 1.0 M Na-acetate (80 mL/hr), and 7.5 mL fractions are collected. Each fraction is assayed for cAMP- and cGMP- metabolizing PDE activity. Fractions eluting at approximately 0.6 M Na-acetate, and containing cAMP but not cGMP metabolic activity are pooled and used as a PDE stock solution for assaying PDE IV inhibitory activity.

PDE IV activity is assayed [as described in Thompson et al., Advances in Cyclic Nucleotide

10,

Research, 69 (1979)] at 30°C in a reaction mixture containing: 10 mM Tris-HCl (pH 7.8), 5 mM MgCl<sub>2</sub>, 1 mM β-mercaptoethanol, 1 μM <sup>3</sup>H-cAMP, 10 μM CI-930, PDE IV stock solution, and the desired concentration of test compound. CI-930 is included as an inhibitor of the cyclic GMP-sensitive, cyclic AMP-selective PDE (PDE III) that is also present in the PDE IV stock solution when prepared as described above. The ability of a test compound to inhibit PDE IV is determined by measuring the reduction in cAMP metabolism produced by the test compound and expressing it as a percentage of the reduction induced by 10 μM rolipram, a potent inhibitor of PDE IV [see Beavo, Advances in Second Messenger and Phosphoprotein Research,

22,

1 (1988)]. IC<sub>50</sub>s are calculated for each test compound as the concentration of test compound that inhibits PDE IV by 50%.

When tested in this assay, the compounds of the invention give the following results.

Table 1

Compound of Example No.	IC <sub>50</sub> of PDE IV
